(Received: Nov.22, 2002; Revised: July 20, 2003; Accepted:July 28.2003)

ABSTRACT

Simple state-space formulas are derived for all controllers solving a standard $H_\infty$ problem. In this paper, we assume that the systems are finite dimension, continuous-time, linear and time-invariant. There are efficient algorithms to solve Linear Matrix Inequalities. It is enough to reduce the $H_\infty$ problem to a linear matrix inequality by using Riccati inequality.

Key Words: State-space, Riccati inequalities, $H_\infty$ control.

AMS Subject Classifications: 93B36, 93B52, 93D25, 93B17, 93C05.

1. INTRODUCTION

$H_\infty$ control that tried to provide answers to plant uncertainty under problem. This control problem was first formulated by Zames [10] and is developed in Zames and Francis [12] and Kimura [7]. Most of the solution techniques available at that time involved analytic functions, (Nevanlinna-Pick Interpolation) or operator-theoretic methods [1], [8]. The early attempts to solve these problems were based in the frequency domain (see, [4]). Many papers have been published in $H_\infty$ control theory (see, [3], [4], [10], [11]).

Additional progress on the $2 \times 2$-block problem came from Ball and Cohen [2], who gave a state space solution involving three Riccati equations. In addition to these, Youla parametrization and $2 \times 2$-block problem techniques have played an important role in $H_\infty$ theory. Consider the transfer function $G(s)$ in $H_\infty$ control, and compare transfer functions with their norm. The $H_\infty$ norm of transfer function is defined by

$$\|G(s)\|_\infty = \sup_{\omega \in \mathbb{R}} |G(i\omega)|$$
The transfer function of a system with state-space matrices \([A;B;C;D]\) is given by.
\[
G(s) = C(sI - A)^{-1}B + D .
\]

We will develop a state-space theory by following an approach based on the work of Gahinet [6] and relevance here Özdemir [9]. Throughout this paper, we assume that the systems are finite dimension, continuous-time, linear and time-invariant.

The following notation will be used; \(\ker M\) is null space, \(\mathbb{K} = \mathbb{R}\) or \(\mathbb{C}\). Also \(\lambda(A)\), \(\sigma(A)\) are eigenvalue and singular value of \(A\), respectively. \(E^\dagger\) is the Moore-Pseudo inverse of \(E\). \(N^T\) is the transpose of \(N\). \(V^*\) is Complex conjugate transpose of a matrix \(V\). In addition \(P > 0\) and \(P < 0\) denote the matrix \(P\) is positive and negative definite, respectively. Moreover, \(A \in \mathbb{R}^{n \times n}\) is a \(n \times n\) matrix. Finally as usual notation, the transfer matrix of the linear system, defined as \(G(s) = C(sI - A)^{-1}B + D\).

2. STATEMENT AND MODIFICATION OF THE \(H_{\infty}\) PROBLEM

Consider a linear time-invariant plant \(G(s)\) with state-space equations

\[
\begin{align*}
\dot{x} &= Ax + B_1w + B_2u, \quad x(0) = x^0 \\
\sum_j y_j &= C_2x + D_{21}w + D_{22}u \\
z &= C_1x + D_{11}w + D_{12}u
\end{align*}
\]

where the matrices

\[
(A, B_1, B_2, C_1, C_2) \in \mathbb{K}^{n \times n} \times \mathbb{K}^{n \times l} \times \mathbb{K}^{n \times m} \times \mathbb{K}^{q \times n} \times \mathbb{K}^{p \times n},
\]

\[
(D_{11}, D_{12}, D_{21}, D_{22}) \in \mathbb{K}^{q \times l} \times \mathbb{K}^{q \times m} \times \mathbb{K}^{p \times l} \times \mathbb{K}^{p \times m}.
\]

We regard \(u\) as a control input, \(y\) the measured output, \(w\) an unknown disturbance input and \(z\) the controlled output. This is very general model since it allows for each of \(x, u, w\) to affect both \(y, z\) and \(\mathbb{K} = \mathbb{R}\) or \(\mathbb{C}\). This can be accommodated by setting

\[
B_2 = \begin{bmatrix} B_2^1 & 0 & 0 \end{bmatrix}, \quad D_{22} = \begin{bmatrix} D_{22}^1 & D_{22}^2 \\ 0 & 0 \end{bmatrix}, \quad D_{12} = \begin{bmatrix} 0 & 0 \\ D_{12}^3 \end{bmatrix}
\]
Similarly with respect to $w$,

$$B_1 = \begin{bmatrix} B_1^1 & 0 & 0 \end{bmatrix}, \quad D_{21} = \begin{bmatrix} 0 & D_{21}^2 & 0 \end{bmatrix}, \quad D_{11} = \begin{bmatrix} 0 & 0 & D_{11}^3 \end{bmatrix}$$

All the norms of vectors will be Euclidean with the corresponding induced norms for matrices. The transfer function $G(\cdot)$ from $\begin{bmatrix} w \\ u \end{bmatrix}$ to $\begin{bmatrix} z \\ y \end{bmatrix}$ is,

$$G(s) = \begin{pmatrix} D_{11} & D_{12} \\ D_{21} & D_{22} \end{pmatrix} + \begin{pmatrix} C_1 \\ C_2 \end{pmatrix}(sI - A)^{-1}(B_1, B_2), \quad s \in \mathbb{C} / \sigma(A)$$

$$= \begin{pmatrix} G_{11}(s) & G_{12}(s) \\ G_{21}(s) & G_{22}(s) \end{pmatrix}$$

This realization is taken minimal and $n$ denotes its order $A \in \mathbb{K}^{n \times n}$. We suppose that there is a compensator of the form

$$\sum_K: \begin{cases} \dot{x} = A_K \dot{x} + B_1 w + B_K y, \quad \dot{x}(0) = \dot{x}^0, \\ u = C_K \dot{x} + D_K y \end{cases}$$

where

$$(A_K, B_K, C_K, D_K) \in \mathbb{K}^{n \times \hat{n}} \times \mathbb{K}^{\hat{n} \times p} \times \mathbb{K}^{m \times \hat{n}} \times \mathbb{K}^{m \times p}, \quad \hat{n}, m, p, \text{ are integer.}$$

So the transfer function of the controller is

$$K(s) = D_K + C_K(I - A_K)^{-1}B_K, \quad s \in \mathbb{C} \setminus \sigma(A_K)$$

The interconnection system $\sum \times \sum_K$ is well-posed. It is necessary that $I - D_{22}D_K$ is invertible. Throughout this paper we assume that

(A.1) $(A, B_2)$ is stabilizable,
(A.2) $(A, C_2)$ is detectable,
(A.3) $I - D_{22}D_K$ is invertible.
Figure 1: Interconnection system

As a result of the above formulation, the continuous-time basic block diagram $H_{\infty}$ model problem can be shown as in Figure 1. $G$ is the generalized plant and $K$ is controller. Now the closed-loop system is

$$
\dot{x} = A_{cl}x + B_{cl}w,
$$

$$
z = C_{cl}\hat{x} + D_{cl}w,
$$

where $\hat{x} = \begin{bmatrix} x \\ \dot{x} \end{bmatrix} \in \mathbb{K}^{n+\hat{n}}$, and

$$
A_{cl} = \begin{bmatrix} A + B_{2}D_{K}(I - D_{22}D_{K})^{-1}C_{2} & B_{2}(I - D_{K}D_{22})^{-1}C_{K} \\ B_{K}(I - D_{22}D_{K})^{-1}D_{22}C_{2} & A_{K} + B_{K}(I - D_{22}D_{K})^{-1}D_{22}C_{K}D_{22} \end{bmatrix},
$$

$$
B_{cl} = \begin{bmatrix} B_{1} + B_{2}D_{K}(I - D_{22}D_{K})^{-1}C_{2} \\ D_{K}(I - D_{22}D_{K})^{-1}C_{2} \end{bmatrix},
$$

$$
C_{cl} = \begin{bmatrix} C_{1} + D_{12}D_{K}(I - D_{22}D_{K})^{-1}C_{2} & D_{12}(I - D_{K}D_{22})^{-1}C_{K} \end{bmatrix},
$$

$$
D_{cl} = \begin{bmatrix} D_{11} + D_{12}D_{K}(I - D_{22}D_{K})^{-1}D_{21} \end{bmatrix},
$$

Let $F(G,K)(s)$ denote the closed-loop transfer function from $w$ to $z$ under dynamic output feedback $u = K(s)y$.

$$
F(G,K)(s) = D_{cl} + C_{cl}(sI - A_{cl})^{-1}B_{cl}
$$

$$
= G_{11}(s) + G_{12}(s)K(s)(I - G_{22}(s)K(s))^{-1}G_{21}(s) \quad s \in \mathbb{C} \setminus \sigma(A_{cl}).
$$
Our aim is to characterize all those dynamic output feedback control $K(s)$, i.e. all quadruple $(AK, BK, CK, DK)$ for the interconnection system $\Sigma \times \Sigma_K$ is well-posed and the resulting closed-loop system, whose transfer matrix is $F$, internally stable such that for some $\gamma > 0$, the transfer function $F(G, K)$ satisfies

$$\|F(G, K)(\cdot)\|_{H_\infty} = \max_{\omega \in \mathbb{R}} \|F(G, K)(i\omega)\| < \gamma.$$ 

3. PRELIMINARY MATERIAL

We will use the notation $D \in H_n^+(K), Q \in H_n^+(K), D|_{\ker Q} > 0$, to mean $\langle x, Dx \rangle > 0, x \in \ker Q, x \neq 0$ with no constraint on $D$ in the case where $\ker Q = \{0\}$. The following lemma will be needed.

Lemma 3.1. The block matrix

$$\begin{pmatrix} P & N \\ N^T & Q \end{pmatrix} \succeq 0$$

is equivalent to

$$\begin{cases} Q < N \\ P - NQ^{-1}N^T < 0. \end{cases}$$

In the sequel, $P - NQ^{-1}N^T$ will be referred to as the Schur complement of $Q$ (see, [6]).

Lemma 3.2. Suppose $D \in H_n(K), Q \in H_n^+(K)$ and $D|_{\ker Q} > 0$. Then there exists $\alpha > 0$ such that $D + \alpha Q > 0$. Conversely if $D + \alpha Q > 0$ for some $\alpha > 0$, then $D|_{\ker Q} > 0$.

Proof. With respect to the decomposition

$$K^n = (\ker Q)^\perp \oplus \ker Q$$

$D$ and $Q$ have the form

$$D = \begin{bmatrix} D_1 & D_2 \\ D_2^* & D_3 \end{bmatrix}, \quad Q = \begin{bmatrix} Q_1 & 0 \\ 0 & 0 \end{bmatrix}, \quad D_3 > 0, Q_1 > 0$$

Hence

$$D + \alpha Q_1 = \begin{bmatrix} D_1 + \alpha Q_1 & D_2 \\ D_2^* & D_3 \end{bmatrix} > 0$$
follows for sufficiently large $\alpha$ from Lemma 3.1, since

$$D_3 > 0, \quad D_1 + \alpha Q_1 > 0, \quad D_1 + \alpha Q_1 - D_2 D_3^{-1} D_3^* > 0, \quad \alpha >> 1$$

The converse is obvious. \hfill \Box

Lemma 3.3 (Gahinet, [5]) Suppose $E \in H_n(K), \ Q \in H_m(K), \ M \in K^{k \times m}, L \in K^{n \times m}$. Then there exists a matrix $X \in K^{n \times l}$ satisfying

$$\begin{align*}
(L + XM)E^*(L + XM) &< Q \\
(L + XM)E^* &< Q
\end{align*}$$

(3.1)

if and only if $L^* EL < Q$ on $ker M$.

Proof. Suppose $V_2 \in K^{n \times k}$ that is a matrix whose columns a basis of $ker M$. Then (3.3) implies $V_2^* L^* EL V_2 < V_2^* Q V_2$, i.e. $L^* EL < Q$ on $ker M$. Replacing $L$ and $X$, respectively, by $LQ^{-\frac{1}{2}}$ and $XQ^{-\frac{1}{2}}$. We see that we may assume without loss of generality that $Q = I_n$. Now choose $V_1 \in K^{m \times (m-k)}$ such that $V = [V_1 \ V_2]$ is unitary matrix. Write

$$L[V_1 \ V_2] = [L_1 \ L_2], \ M[V_1 \ V_2] = [M_1 \ 0]$$

pre and post multiplying by $V^*$ and $V$, respectively, we see that (3.1) is equivalent to

$$\begin{bmatrix}
(L_1 + XM_1)^* E(L_1 + XM_1) & (L_1 + XM_1)^* EL_2 \\
L_2^* E(L_1 + XM_1) & L_2^* EL_2
\end{bmatrix} < Q = I_n$$

But since $M_1$ is full column rank, there exists a matrix $X \in K^{n \times l}$ such that $(L_1 + XM_1) = 0$. This proves (3.1). \hfill \Box

Lemma 3.4. (Bounded Real Lemma, [5],[6]) Consider a continuous time transfer matrix $T(s)$ of (not necessarily minimal) realization

$$T(s) = D + C(sI - A)^{-1} B.$$ 

The following statements are equivalent:

(a) $A$ is stable in the continuous-time since $\text{Re}(\lambda(A)) < 0$ and

$$\|D + C(sI - A)^{-1} B\| < \gamma, \quad \gamma > 0.$$
(b) There exists a symmetric positive definite solution $X$ to the LMI:

$$
\begin{bmatrix}
A^T X & X B & C^T \\
B^T X & -\gamma I & D^T \\
C & D & -\gamma I
\end{bmatrix} < 0
$$

(3.2)

Note that LMI (3.2) equivalent to

$$
\begin{align*}
&\sigma_{\text{max}}(D) < \gamma \\
&A^T X + X A + \gamma^{-1} C^T C + \gamma(\gamma^{-1} C^T D + X B)(\gamma^2 I - D^T D)^{-1}(\gamma^{-1} C^T D + X B)^T < 0.
\end{align*}
$$

Lemma 3.5. (Projection Lemma) Suppose $N \in \mathbb{K}^{1 \times m}$, $H \in \mathbb{K}^{n \times m}$ and $D \in H_m(\mathbb{K})$. Then the linear matrix inequality

$$
D + N^* X^* H + H^* X N < 0
$$

(3.3) has a solution $X \in \mathbb{K}^{n \times l}$ if and only if $D$ is negative definite on $\ker N$ and on $\ker H$.

Proof. The necessity of the condition is obvious. To prove sufficiency, we assume that $D$ is negative definite on $\ker N$ and on $\ker H$. For every $\gamma > 0$, (3.3) is equivalent to

$$(\gamma X N + \gamma^{-1} H) ^* (\gamma X N + \gamma^{-1} H) < -D + \gamma^2 N^* X^* X N + \gamma^{-2} H^* H.$$  

By assumption and Lemma 3.2

$$-D + \gamma^{-2} H^* H > 0 \quad \text{for} \quad \gamma \quad \text{sufficiently small.}$$

We can apply Lemma 3.3 with $E = I_n$, $\bar{M} = \gamma N$, $L = \gamma^{-1} H$ and

$$Q = -D + \gamma^{-2} H^* H,$$

since $L^* E L = \gamma^{-2} H^* H < -D + \gamma^{-2} H^* H = Q$ on $\ker N$, since $-D > 0$ on $\ker N$ by assumption. Hence there exists $X \in \mathbb{K}^{n \times l}$ such that

$$(\gamma X N + \gamma^{-1} H) ^* (\gamma X N + \gamma^{-1} H) < -D + \gamma^{-2} H^* H \leq -D + \gamma^2 N^* X^* X N + \gamma^{-2} H^* H \quad \square$$

All the control information is collected in a single matrix

$$M_K = \begin{bmatrix}
A_K & B_K \\
C_K & D_K
\end{bmatrix} \in \mathbb{K}^{(n+\hat{n}) \times (n+\hat{n})}.$$

4. Main Results

The following notation will be used.
\[
A^0 = \begin{bmatrix} A & 0 \\ 0 & 0_n \end{bmatrix}, \quad B^0 = \begin{bmatrix} B_1 \\ 0 \end{bmatrix}, \quad C^0 = \begin{bmatrix} C_1 & 0 \end{bmatrix}, \quad D^0_{12} = \begin{bmatrix} 0 & D_{12} \end{bmatrix}.
\]

\[
B^I = \begin{bmatrix} 0 & B_2 \\ I_n & 0 \end{bmatrix}, \quad C^I = \begin{bmatrix} 0 & I_n \\ C_2 & 0 \end{bmatrix}, \quad D^0_{21} = \begin{bmatrix} 0 \\ D_{21} \end{bmatrix}.
\]

Then the closed loop matrices can be written as

\[
A_{cl} = A^0 + B^I M_K C^I, \quad B_{cl} = B^0 + B^I M_K D^0_{21}, \quad C_{cl} = D^0 + D^0_{12} M_K C^I, \quad D_{cl} = D_{11} + D^0_{12} M_K D^0_{21}.
\]

**Theorem 4.1.** The following are equivalent:

(i) There exists a stabilizing dynamic output controller \( K(\cdot) \) such that

\[
\max_{\omega \in \mathbb{R}} \| F(G, K)(i\omega) \| < \gamma \tag{4.1}
\]

(ii) There exists a \( X_{cl} \in H_{n+n}, X_{cl} > 0 \) such that the matrix \( \Phi_{X_{cl}} \) is negative definite on \( \ker U \) and \( \Psi_{X_{cl}} \) is negative on \( \ker V \), where

\[
\Phi_{X_{cl}} = \begin{bmatrix}
X^{-1}_{cl} A^0 + X^{-1}_{cl} (A^0)^* & B^0 & X^{-1}_{cl} (C^0)^* \\
(B^0)^* & -\gamma I & D \\
C^0 X^{-1}_{cl} & D_{11} & -\gamma I
\end{bmatrix},
\]

\[
\Psi_{X_{cl}} = \begin{bmatrix}
(A^0)^* X_{cl} + X_{cl} A^0 & X_{cl} B^0 & (C^0)^* \\
(B^0)^* X_{cl} & -\gamma I & D_{11}^* \\
C^0 & D_{11} & -\gamma I
\end{bmatrix},
\]

and

\[
U = \begin{bmatrix} (B^I)^*, 0_{(n+m)\times I}, (D^0_{12})^* \end{bmatrix}, \quad V = \begin{bmatrix} C^I, D^0_{21}, 0_{(n+p)\times q} \end{bmatrix} \tag{4.2}
\]

**Proof.** Applying Lemma 3.4 with \( A = A_{cl} \quad B = B_{cl} \) we see that \( K(s) = D_K + C_K (sI - A)^{-1} B_K \) is a stabilizing controller satisfying (4.1) if and only if there exists \( P_{cl} \in H_{n+n}, P_{cl} < 0 \), such that
\[
\begin{bmatrix}
P_{cl}A_{cl} + A_{cl}^*P_{cl} - C_{cl}^*C_{cl} & P_{cl} - C_{cl}^*D_{cl} \\
B_{cl}^*P_{cl} - D_{cl}^*C_{cl} & -\gamma^2 I - D_{cl}^*D_{cl}
\end{bmatrix} > 0.
\]

We see that this is equivalent to the existence of \(X_{cl} \in H_{n+n}, X_{cl} > 0\) such that

\[
\begin{bmatrix}
A_{cl}^*X_{cl} + X_{cl}A_{cl} & X_{cl}B_{cl} & C_{cl}^* \\
B_{cl}^*X_{cl} & -\gamma & D_{cl}^* \\
C_{cl}^* & D_{cl} & -\gamma
\end{bmatrix} < 0. \tag{4.3}
\]

Substituting for \(A_{cb}, B_{cb}, C_{cb}, D_{cb}\) (4.3) becomes

\[
\begin{bmatrix}
(A^0 + B^1 M_K C^I)^* X_{cl} + X_{cl} (A^0 + B^1 M_K C^I) & X_{cl} (B^0 + B^1 M_K D_{21}^0) & (C^0 + D_{12}^0 M_K C^I)^* \\
(B^0 + B^1 M_K D_{21}^0)^* X_{cl} & -\gamma & D_{11}^0 + D_{12}^0 M_K D_{21}^0 \\
C^0 + D_{12}^0 M_K C^I & D_{11}^0 + D_{12}^0 M_K D_{21}^0 & -\gamma
\end{bmatrix} < 0.
\]

or

\[
\Psi_{X_{cl}} + \begin{bmatrix}
X_{cl} B^K^* \\
0 \\
D_{12}^0
\end{bmatrix} M_K \begin{bmatrix}
C^I, D_{21}^0, 0 \\
0, C^I, D_{21}^0
\end{bmatrix}^* M_K^* \begin{bmatrix}
X_{cl} B^K^* \\
0 \\
D_{12}^0
\end{bmatrix} < 0.
\]

That is

\[
\Psi_{X_{cl}} + U_{X_{cl}}^* M_K V + V^* M_K^* U_{X_{cl}} < 0. \tag{4.4}
\]

where \(U_{X_{cl}} = \begin{bmatrix} (B^1)^* X_{cl}, 0, (D_{21}^0)^* \end{bmatrix}^*\). We now use Lemma 3.5 with \(D = \Psi_{X_{cl}}, N = U_{X_{cl}}, H = V\) and \(X = M_K\), to conclude that (i) is equivalent to \(\Psi_{X_{cl}}\) being negative definite on \(ker V\) and \(ker UX_{cl}\). To complete the proof, note that

\[
U_{X_{cl}} = U \begin{bmatrix}
X_{cl} & 0 & 0 \\
0 & I & 0 \\
0 & 0 & I
\end{bmatrix}, \quad \text{and} \quad \Phi_{X_{cl}} = \begin{bmatrix}
X_{cl}^{-1} & 0 & 0 \\
0 & I & 0 \\
0 & 0 & I
\end{bmatrix} \Psi_{X_{cl}} \begin{bmatrix}
X_{cl}^{-1} & 0 & 0 \\
0 & I & 0 \\
0 & 0 & I
\end{bmatrix}.
\]

The characterization in the above theorem is awkward since it involves both \(X_{cl}\) and its inverse. However a simpler form can be obtained by partitioning \(X_{cl}\) and \(X_{cl}^{-1}\). In order to show this we need the following lemma
Lemma 4.2. Let \( n, \hat{n} \geq 1 \). Suppose \( X \in H_{n+\hat{n}}(K) \) and its inverse \( X^{-1} \) are partitioned as follows

\[
X = \begin{bmatrix} S & N \\ N^* & Q \end{bmatrix}, \quad X^{-1} = \begin{bmatrix} P & M \\ M^* & T \end{bmatrix}, \quad P, S \in H_n(K),
\]

and \( X > 0 \), then

\[
S \geq P^{-1} > 0 \quad \text{and rank} \left[ S - P^{-1} \right] \leq \hat{n}.
\]

(4.5)

Conversely, if \( P, S \in H_n(K) \) are given such that (4.6) is satisfied, then there exists \( X \in H_{n+\hat{n}}(K), X > 0 \) such that \( X \) and its inverse can be partitioned as in (4.5) (with suitable \( N, Q, M, T \)).

Proof. Suppose that

\[
X = \begin{bmatrix} S & N \\ N^* & Q \end{bmatrix}, \quad X^{-1} = \begin{bmatrix} P & M \\ M^* & T \end{bmatrix}, \quad P, S \in H_n(K)
\]

Then

\[
SP + NM^* = I_n, \quad N^*P + QM^* = 0
\]

and since \( X > 0 \), we have

\[
S > 0, \quad Q > 0, \quad S - NQ^{-1}N^* > 0,
\]

\[
P > 0, \quad T > 0, \quad P - MT^{-1}M^* > 0.
\]

Now \( SP - NQ^{-1}N^*P = I_n \) and hence \( S - NQ^{-1}N^* = P^{-1} \). So

\[
S \geq P^{-1} > 0 \quad \text{and rank} \left[ S - P^{-1} \right] \leq \hat{n}.
\]

Conversely, assume that \( P, S \in H_n(K) \) are given such that the above conditions are satisfied. Let

\[
r = \text{rank}(S - P^{-1}) \leq \hat{n}.
\]

It sufficiency to show that there exists \( M, N \in K^{nxr}, Q, T \in H_r(K), Q > 0 \) such that

\[
SP + NM^* = I_n, N^*P + QM^* = 0, \quad SM + NT = 0, \quad N^*M + QT = I_{\hat{n}}
\]

(4.7)

In fact, setting

\[
X = \begin{bmatrix} S & 0 & 0 \\ N^* & Q & 0 \\ 0 & 0 & I_{\hat{n}-r} \end{bmatrix} \in H_{n+\hat{n}}(K),
\]
We obtain

\[
X^{-1} = \begin{bmatrix}
P & 0 & 0 \\
M^* & T & 0 \\
0 & 0 & I_{\hat{n}-r}
\end{bmatrix}
\]

\(X>0\) because \(Q>0\) and \(S - NQ^{-1}N^* = P^{-1} > 0\). We now construct matrices \(M, N, Q, T\) such that (4.7) holds and \(Q > 0\). Let \([U \ V] \in \mathbb{K}^{n \times n}\) be a unitary matrix with \(U \in \mathbb{K}^{n \times (n-r)}\) in \(\ker(S - P^{-1})\) and define

\[
N = \left[\text{rank}(S - P^{-1})\right]^{1/2} Y, \quad M = -PN, \quad Q = I_r, \quad T = I_r - N^*M
\]

Since \(VV^*\) is the orthogonal projection from \(\mathbb{K}^n\) into the linear subspace in \(\ker(S - P^{-1})\), we have

\[
NN^* = \left[\text{rank}(S - P^{-1})\right]^{1/2} VV^* \left[\text{rank}(S - P^{-1})\right]^{1/2} = (S - P^{-1}).
\]

Using this fact the equations in (4.7) are obtained by direct calculation.

**Theorem 4.3.** For any \(\gamma > 0\), the following are equivalent:

(i) There exists a stabilizing dynamic output feedback controller \(K(\cdot)\) of dimension \(\hat{n}\) such that

\[
\max_{w \in \mathbb{R}^{-}} \|F(G,K)(iw)\| < \gamma.
\]  

(ii) There exists \((P,S) \in H_n \times H_n\), \(P > 0, S > 0\) such that

\[
S \geq \gamma^2 P^{-1} > 0 \quad \text{and} \quad \text{rank} \left[ S - \gamma^2 P^{-1} \right] \leq \hat{n}
\]  

\[
\begin{bmatrix}
AP + PA^* + B_1B_1^* & PC_1^* + B_1D_1^* \\
C_1P + D_{11}B_1^* & -(\gamma^2 I_q - D_{11}D_{11}^*)
\end{bmatrix} < 0, \quad \text{on} \quad \ker \left[ B_2^* D_{12} \right] \quad (4.10)
\]

\[
\begin{bmatrix}
SA + A^* S + C_1^* C_1 & SB_1 + C_1^* D_{11} \\
B_1^* S + D_{11}^* C_1 & -\gamma^2 I_l - D_{11}^* D_{11}
\end{bmatrix} < 0, \quad \text{on} \quad \ker \left[ C_2 D_{21} \right].
\]  

**Proof.** By the Theorem 4.1 (i) is equivalent to the existence of \(X_{cl} \in H_{n+\hat{n}}\), \(X_{cl} > 0\), such that the matrix \(\Phi_{X_{cl}}\) is negative on \(\ker U\) and \(\Psi_{X_{cl}}\) is negative.
definite on \( \ker V \). Let

\[
X_{\text{cl}} = \begin{bmatrix} S & N \end{bmatrix}, \quad X_{\text{cl}}^{-1} = \begin{bmatrix} P & M \\ M^* & T \end{bmatrix}
\]  

(4.12)

Then

\[
SP + NM^* = I_n, \quad N^* P + QM^* = 0.
\]

Since \( X_{\text{cl}} > 0 \), we have

\[
S > 0, \quad Q > 0, \quad S - NQ^{-1}N^* > 0, \\
P > 0, \quad T > 0, \quad R - MT^{-1}M^* > 0
\]

Now \( SP - NQ^{-1}N^*P = I_n \) and hence \( S - NQ^{-1}N^* = P^{-1} \). So we obtain from Lemma 4.2

\[
S \geq P^{-1} \quad \text{and} \quad \text{rank}[S^{-1}P] \leq \hat{n}.
\]  

(4.13)

Let us consider the condition that \( \Phi_{X_{\text{cl}}} \) is negative definite on \( \ker U \). Partitioning \( \Phi_{X_{\text{cl}}} \) and \( U \), we have

\[
\Psi_{X_{\text{cl}}} = \begin{bmatrix} AP + PA^* & AM & B_1 & PC_1^* \\
M^*A^* & 0 & 0 & M^*C_1^* \\
B_1^* & 0 & -\gamma & D_{11}^* \\
C_1P & C_1M & D_{11} & -\gamma \end{bmatrix}
\]

and

\[
U = \begin{bmatrix} 0 & I_{\hat{n}} & 0 & 0 \\
B_2^* & 0 & 0 & D_{12}^* \end{bmatrix}.
\]

It follows that \( \ker U \) has a basis of the form

\[
U = \begin{bmatrix} U_1 & 0 \\
0 & 0 \\
0 & I_{\hat{1}} \\
U_2 & 0 \end{bmatrix},
\]

where \( \begin{bmatrix} U_1 \\ U_2 \end{bmatrix} \) is basis of \( \ker \begin{bmatrix} B_2^* & D_{12}^* \end{bmatrix} \). Now
\[
\begin{bmatrix}
U_1 & 0 \\
0 & 0 \\
0 & I_t \\
U_2 & 0
\end{bmatrix}
\begin{bmatrix}
AP + PA^* & AM & B_1 & PC_1^* \\
M^*A^* & 0 & 0 & M^*C_1^* \\
B_1^* & 0 & -\gamma & D_{11}^* \\
C_1P & C_1M & D_{11} & -\gamma
\end{bmatrix}
\begin{bmatrix}
U_1 & 0 \\
0 & I_t \\
0 & 0 \\
U_2 & 0
\end{bmatrix} =
\begin{bmatrix}
U_1 & 0 \\
0 & I_t \\
U_2 & 0 \\
0 & I_t
\end{bmatrix}
\begin{bmatrix}
AP + PA^* & B_1 & PC_1^* \\
B_1^* & -\gamma & D_{11}^* \\
C_1P & D_{11} & -\gamma
\end{bmatrix}
\begin{bmatrix}
U_1 & 0 \\
U_2 & 0
\end{bmatrix} < 0.
\]

Interchanging rows and columns we see that \( \Phi_{X_d} \) is negative definite on \( \ker U \) if and only if

\[
\begin{bmatrix}
U_1 & 0 \\
U_2 & 0 \\
0 & I_t
\end{bmatrix}
\begin{bmatrix}
AP + PA^* & PC_1^* & B_1 \\
C_1P & -\gamma & D_{11} \\
B_1^* & D_{11}^* & -\gamma
\end{bmatrix}
\begin{bmatrix}
U_1 & 0 \\
U_2 & 0
\end{bmatrix} < 0.
\]

But this is equivalent to

\[
\begin{bmatrix}
U_1^* & U_2^*
\end{bmatrix}
\begin{bmatrix}
AP + PA^* & PC_1^* \\
C_1P & -\gamma \\
B_1^* & D_{11}^*
\end{bmatrix}
\begin{bmatrix}
U_1 \\
U_2
\end{bmatrix}
\begin{bmatrix}
B_1 \\
D_{11}
\end{bmatrix} < 0.
\]

By the negativity Lemma 3.4, the above holds if and only if

\[
\begin{bmatrix}
U_1^* & U_2^*
\end{bmatrix}
\begin{bmatrix}
AP + PA^* & PC_1^* \\
C_1P & -\gamma \\
B_1^* & D_{11}^*
\end{bmatrix} + \gamma^{-1}
\begin{bmatrix}
B_1 \\
D_{11}
\end{bmatrix}
\begin{bmatrix}
U_1 \\
U_2
\end{bmatrix} < 0.
\]

The transform \( P \rightarrow \gamma^{-1}P \) yields (4.10). (4.11) is proved in similar way and (4.9) obtained form (4.13) after the transformations \( P \rightarrow \gamma^{-1}P, S \rightarrow \gamma^{-1}S \).

Conversely, suppose \( (P, S) \in H_n \times H_n, P > 0, S > 0 \) satisfy the conditions in (ii), we first make the transformation \( (P, S) \rightarrow (\gamma^{-1}P, \gamma^{-1}S) \). Suppose \( \text{rank}[P - S] \leq \hat{n} \), then we may choose a basis so that \( P - S^{-1} = \begin{bmatrix} 0 & 0 \\ 0 & H \end{bmatrix} \), where \( H \in H_{\hat{n}}, H \geq 0 \) and commensurate to this partition.
\( P = \begin{bmatrix} P_{11} & P_{12} \\ P_{12} & P_{22} \end{bmatrix}, \quad S = \begin{bmatrix} S_{11} & S_{12} \\ S_{12}^* & S_{22} \end{bmatrix} \).

Applying the transform \( P \to \gamma P, \quad S \to \gamma S \) and using Lemma 4.2 we obtain that there exist \( N, M \in K^{n \times d}, Q, T \in H_1(K) \) such that

\[
X_{cl} = \begin{bmatrix} S & N \\ N^* & Q \end{bmatrix}, \quad X_{cl}^{-1} = \begin{bmatrix} P & M \\ M^* & T \end{bmatrix}.
\]

Now define \( \Psi_{X_{cl}}, \Phi_{X_{cl}} \) as in Theorem 4.1. We have just proved that (4.10), (4.11) imply that the matrix \( \Phi_{X_{cl}} \) is negative definite on \( \ker U \) and \( \Psi_{X_{cl}} \) is negative definite on \( \ker V \). But this is equivalent to (i).

There are now efficient algorithms for solving linear matrix inequalities (LMIs) (see [6]). Given that \( P > 0, S > 0 \) satisfying (4.9), (4.10) and (4.11). \( \Psi_{X_{cl}} \) can be constructed as in the above proof, then using (4.4) feasible control matrices \( M_k \) are obtained. Nevertheless, we continue the analysis of (4.10) and (4.11). The objectives are:

- to remove the kernel constraint by reducing the dimension in the inequalities,
- to show that the reduced inequalities can be replaced by Riccati inequalities of lower dimension,
- as an alternative to the above we will show that by introducing two scalar parameters, (4.10) and (4.11) can be replaced directly by two Riccati inequalities in \( H_n \).

These results will be used to obtain a Riccati equation based characterisation. First we assume that \( D_{12} \) and \( D_{21}^* \) have full column rank. Then later we will show how this assumption can be removed. Since we want to state a result which covers both (4.10) and (4.11), we will use the following notations.

\[
(A, B, C, Q, E, V, W) \in K^{n \times n} \times K^{n \times m} \times K^{q \times n} \times K^{q \times q} \times K^{q \times m} \times K^{n \times q} \times K^{n \times n}
\]

(4.14)

\[
A_0 = A - BE^\top C, \quad V_q = V + BE^\top (\gamma^2 I - Q)
\]

(4.15)

\[
W_0 = W - BE^\top V^* - V(BE^\top)^* - BE^\top (\gamma^2 I - Q)(BE^\top)^*,
\]

(4.16)

\[
V_0 = W_Q(I - EE^\top), \quad Q_0 = (I - EE^\top)Q(I - EE^\top), \quad C_0 = (I - EE^\top)C
\]

(4.17)
where $E^\dagger$ is the \textit{pseudo inverse} of $E$ and since we will assume that $E$ is of full column rank, we have $E^\dagger = (E^*E)^{-1}E^*$.

\textbf{Lemma 4.4.} Suppose (4.14)-(4.17) hold with $E$ being full column rank. Then there exists $P \in H_n, P > 0$, such that

$$
\begin{bmatrix}
AP + PA^* + W & PC^* + V \\
CP + V^* & -\gamma^2 I + Q
\end{bmatrix} < 0 \text{ on } \ker\begin{bmatrix}
B^* & E^*
\end{bmatrix}
$$

(4.18)

if and only if $P > 0$ satisfies

$$\gamma^2 I > Q_0 \tag{4.19a}$$

$$A_0P + PA^* + W_0 + (PC_0^* + V_0)(\gamma^2 I - Q_0)^{-1}(PC_0^* + V_0)^* < 0. \tag{4.19b}$$

\textbf{Proof.} Let $U_{12}$ be a basis for $E^* = \text{Range}(I - EE^\dagger)$ with $U_{12}^*U_{12} = I$. Then we may choose

$$
\begin{bmatrix}
I & 0 \\
-(BE^\dagger)^* & U_{12}
\end{bmatrix}
$$

as a basis for $\ker\begin{bmatrix}
B^* & E^*
\end{bmatrix}$. So (4.18) is equivalent to

$$
\begin{bmatrix}
I & 0 \\
-(BE^\dagger)^* & U_{12}
\end{bmatrix}^* \begin{bmatrix}
AP + PA^* + W & PC^* + V \\
CP + V^* & -\gamma^2 I + Q
\end{bmatrix} \begin{bmatrix}
I & 0 \\
-(BE^\dagger)^* & U_{12}
\end{bmatrix} < 0.
$$

The \{11\} component of the LHS of the above inequality is

$$AP + PA^* + W - BE^\dagger(CP + V^*) - (PC^* + V)(BE^\dagger)^* + BE^\dagger(-\gamma^2 I + Q)(BE^\dagger)^*.$$

The \{12\} component is

$$(PC^* + V + BE^\dagger(\gamma^2 I - Q))U_{12},$$

and the \{22\} is

$$-U_{12}^*(\gamma^2 I - Q)U_{12}.$$

So (4.18) is equivalent to

$$
\begin{bmatrix}
A_0P + PA_0^* + W_0 & (PC^* + V_0)U_{12} \\
U_{12}^*(CP + V_0^*) & -\gamma^2 I + U_{12}^*QU_{12}
\end{bmatrix} < 0.
$$
Then using Lemma 3.4, both of the above are equivalent to $\gamma^2 I > Q_{\ker E^*}$ and the Riccati inequality

$$A_0 P + PA_0^* + W_0 + (PC^* + V_Q)U_{12}(\gamma^2 I - U_{12}^*QU_{12})^{-1}U_{12}^*(PC^* + V_Q)^* < 0$$

(4.20)

But

$$U_{12}(\gamma^2 I - U_{12}^*QU_{12}) = (\gamma^2 I - U_{12}U_{12}^*)^{-1}U_{12}U_{12}^* .$$

Now

$$U_{12}U_{12}^* = (I - EE^\dagger) = (I - EE^\dagger)^2 ,$$

so

$$(\gamma^2 I - U_{12}U_{12}^*)^{-1}U_{12}U_{12}^* = (\gamma^2(I - EE^\dagger)^2 Q)^{-1}(I - EE^\dagger)^2$$

Substitution in (4.20) yields (4.15).

In order to apply this result to (4.9) and (4.10), we have to introduce even more notations.

$$\widetilde{B}_2 = B_2 D_{12}^\dagger, \quad \widetilde{A} = A - \widetilde{B}_2 C_1, \quad \widetilde{B}_1 = B_1 - \widetilde{B}_2 D_{11}$$

(4.21a)

$$\widetilde{C}_1 = (I - D_{12} D_{12}^\dagger) C_1, \quad \widetilde{D}_{11} = (I - D_{12} D_{12}^\dagger) D_{11}, \quad \widetilde{\Pi}_\gamma = \gamma^2 I - \widetilde{D}_{11} \widetilde{D}_{11}^*$$

(4.21b)

and

$$\widetilde{C}_2 = D_{21}^\dagger C_2 , \quad \widetilde{A} = A - B_1 C_2 , \quad \widetilde{C}_1 = C_1 - D_{11} \widetilde{C}_2$$

(4.22a)

$$\widetilde{B}_1 = B_1 (I - D_{21}^\dagger D_{21}) , \quad \widetilde{D}_{11} = D_{11} (I - D_{21}^\dagger D_{21}) , \quad \widetilde{\Pi}_\gamma = \gamma^2 I - \widetilde{D}_{11} \widetilde{D}_{11}^*$$

(4.22b)

**Proposition 4.5.** Suppose $D_{12}$ and $D_{21}^*$ have full column rank. Then the followings are equivalent:

(i) There exists a stabilizing dynamic output feedback controller $K(\cdot)$ of dimension $\hat{n}$ such that

$$\max_{w \in \mathbb{R}^n} \|F(G,K)(tw)\| < \gamma .$$

(ii) There exists $(P,S) \in H_\infty \times H_\infty, P > 0, S > 0$ such that

$$\gamma > \max \|\widetilde{D}_{11}\| \|\widetilde{D}_{11}\| ,$$

(4.23a)
\[ S \geq \gamma^2 P^{-1} \quad \text{and} \quad \text{rank} \left[ S - \gamma^2 P^{-1} \right] \leq \tilde{n}, \quad (4.23b) \]

\[ \tilde{A}P + P\tilde{A}^* - \gamma^2 \tilde{B}_2^* \tilde{B}_2^* + \tilde{B}_1^* \tilde{B}_1^* + (P\tilde{C}_1^* + \tilde{B}_1^* \tilde{D}_1) \tilde{\Pi}_1^{-1} (P\tilde{C}_1^* + \tilde{B}_1^* \tilde{D}_1)^* < 0 \quad (4.24) \]

\[ \tilde{A}^* S + S \tilde{A} - \gamma^2 \tilde{C}_2^* \tilde{C}_2 + \tilde{C}_1^* \tilde{C}_1 + (S\tilde{B}_1^* + \tilde{C}_1^* \tilde{D}_1) \tilde{\Pi}_1^{-1} (S\tilde{B}_1 + \tilde{C}_1^* \tilde{D}_1)^* < 0. \quad (4.25) \]

**Proof.** Let

\[ B = B_2, \quad E = D_{12}, \quad W = B_1^* B_1, \quad C = C_1, \quad V = B_1^* D_{11}, \quad Q = D_{11}^* D_{11}^* \]

and applying Lemma 4.4, we see that (4.18) is equivalent to the first inequality in (4.23a), together with the Riccati inequality

\[ A_0 P + PA_0^* + W_0 + (PC_0^* + V_0)(\gamma^2 I - Q_0)^{-1}(PC_0^* + V_0)^* < 0, \]

where

\[ A_0 = A - B_2 D_{12}^1 C_1 = A, \quad C_0 = (I - D_{12} D_{12}^1) C_1 = \tilde{C}_1 \]

\[ V_0 = [B_1 D_{11}^* + B_2 D_{12}^1 (\gamma^2 I - D_{11} D_{12}^1)] (I - D_{12} D_{12}^1) \]

\[ = -\tilde{B}_1 D_{11}^* + \gamma^2 B_2 D_{12}^1 (I - D_{12} D_{12}^1) \]

But

\[ D_{12}^1 D_{12} D_{12}^1 = (D_{12}^* D_{12})^{-1} D_{12}^* D_{12} D_{12}^1 = D_{12}^1 \]

and hence \( V_0 = -\tilde{B}_1 D_{11}^* \).

\[ Q_0 = (I - D_{12} D_{12}^1) D_{11} D_{11}^* (I - D_{12} D_{12}^1) = \tilde{D}_{11}^* \tilde{D}_{11}^* \]

\[ W_0 = B_1^* B_1 - B_2 D_{12}^1 D_{11} B_1^* - B_1 D_{11}^* (B_2 D_{12}^1)^* - B_2 D_{12}^1 (\gamma^2 I - D_{11} D_{11}^*) (B_2 D_{12}^1)^* \]

\[ = -\gamma^2 \tilde{B}_2^* \tilde{B}_2 + \tilde{B}_1^* \tilde{B}_1^* \]

Thus, the above Riccati inequality is the same as

\[ \tilde{A}P + P\tilde{A}^* - \gamma^2 \tilde{B}_2^* \tilde{B}_2^* + \tilde{B}_1^* \tilde{B}_1^* + (P\tilde{C}_1^* + \tilde{B}_1^* \tilde{D}_1) \tilde{\Pi}_1^{-1} (P\tilde{C}_1^* + \tilde{B}_1^* \tilde{D}_1)^* < 0. \]

Equation (4.25) and the second inequality in (4.23a) are proved in a similar way. Then the equivalence follows from Theorem 4.3.
REMARKS

Since there are efficient algorithms to solve Linear Matrix Inequality (LMIs), it is enough to reduce the problem \((H_\infty)\) control to a linear matrix inequality by using Riccati inequality. However, this requires \(E\) to be full column rank which implies \(D_{12}\) and \(D_{21}^*\) have full column rank. In the case when \(D_{12}\) and \(D_{21}^*\) do not have full column rank, the reduction algorithm can be used to reduce \(D_{12}\) and \(D_{21}^*\) to the case where the equivalent reduced version of the \(D_{12}\) and \(D_{21}^*\) have full column rank. This can be done by using the Lemma 4.4, and it may require multiple steps, but eventually a reduced form of \(D_{12}\) and \(D_{21}^*\) would be found after which the Riccati inequalities follow. Then the problem can be solved by one of the efficient algorithms which are developed to solve the Linear Matrix Inequality (LMI).
