REFRACTION IN THE CASE OF VELOCITY INCREASING LINEARLY WITH DEPTH AND DIPPING REFRACTOR

TURAN KAYIRAN

Geological Engineering Dept. University of Ankara, Turkey

ABSTRACT

In this paper the time-distance relation for head waves in "dipping refractor" is calculated assuming that the real seismic media may be expressed by the velocity function $V = V_0 (1 + KZ)$, depending on depth. A numerical example is also given.

INTRODUCTION

Horizontal refractor case, with velocity as a function of depth, has been studied by various authors. For the case of dipping refractor, Laski (1972) has developed an algorithm for an approximate solution of time-distance relation with the velocity function taken as $V = V_1$

$$\left[ \frac{L + qz}{L} \right]^\frac{1}{q}$$

where

$q = $ dimensionless constant

$L = $ a constant with the dimension of length

$Z = $ depth below datum.

The greatest difficulty encountered in solving the problem is to find the coordinates of the point at which the seismic ray reaches the refractor under the critical angle.

In this paper the equation giving the coordinates of the above mentioned point has been derived taking the velocity function to be $V = V_0 (1+KZ)$ and thus, the problem is solved.
Calculation of the coordinates

Notation (Fig-1)

\( V_0 = \) velocity at the surface
\( V = \) velocity at \( Z \)
\( Z = \) depth
\( K = \) constant

\( Z = AX + B = \) Equation of the line expressing the refractor
\( V_2 = \) Velocity of the refracting layer.

**Fig (1)**

Equation of the coordinates of the point of incidence at critical angle on the positive \( x \) direction

\[
\sin (\theta_1 + \varphi) = \frac{V_0 (1 + KZ)}{V_2} \]

\[
\sin \theta_1 \cos \varphi + \cos \theta_1 \sin \varphi = \frac{V_0 (1 + KZ)}{V_2} \tag{1}
\]

using \( X = \frac{1}{K \sin \theta_o} (\cos \theta_o - \cos \theta_1) \) and

\[
Z = \frac{1}{K \sin \theta_o} (\sin \theta_1 - \sin \theta_0). \text{ Favre (1958).}
\]
It can be written
\[
\sin \theta_1 = (ZK + 1) \sin \theta_0 \tag{2}
\]
\[
\cos \theta_1 = \cos \theta_0 - K \times \sin \theta_0 \tag{3}
\]
by combination of (2), (3) and (1)
we find \([(KZ + 1) \cos \varphi - KX \sin \varphi] \sin \theta_0 + \sin \varphi \cos \theta_0
\]
\[- V_o (1 + KZ)/V_2 = 0 \tag{4}\]
on the other hand when \(\theta_1\) is eliminated from
\[
X = \frac{1}{K \sin \theta_0} (\cos \theta_0 - \cos \theta_1) \quad \text{and} \quad Z = \frac{1}{K \sin \theta_0} (\sin \theta_1 - \sin \theta_0) \tag{5}\]
and the result is divided by \(K \sin \theta_0\), the following equation is reached
\[
(X^2 + Z^2) K \sin \theta_0 - 2X \cos \theta_0 + 2Z \sin \theta_0 = 0 \tag{6}\]
solving \(\theta_0\) from equation (4) and (6) an equation dependent on \(X\) and \(Z\) can be obtained.

If we multiply both sides of the equations (4) and (6) by \(2X\) and \(\sin \varphi\) respectively and summing the two equations we obtain: \(K \sin \theta_0 \sin \varphi\)
\[
(X^2 + Z^2) + 2X \sin \theta_0 \left(\frac{KZ + 1) \cos \varphi - KX \sin \varphi - KX \sin \varphi}{V_2} \right)
\]
\[- \frac{2X V_o (1 + KZ)}{V_2} = 0 \tag{7}\]
Solving for \(\sin \theta_0\) yields,
\[
\sin \theta_0 = \frac{2 \times d}{V_2 (e + a)} \tag{8}\]
where
\[
d = V_o (1 + KZ) \tag{9}\]
\[
a = 2x \left[(KZ + 1) \cos \varphi - KX \sin \varphi\right] \tag{10}\]
\[
e = K \sin \varphi (X^2 + Z^2) + 2Z \sin \varphi \tag{11}\]
If the value of \(\sin \theta_0\) is placed in the equation (4) it results:
\[
\frac{a d}{V_2 (e + a)} + \sin \varphi \cos \theta_0 - \frac{d}{V_2} = 0 \tag{12}\]
According to (12)
\[
\cos \theta_0 = -\frac{ad}{\sin \varphi \sqrt{V_2 (e + a)}} + \frac{d}{\sin \varphi \sqrt{V_2}} \tag{13}
\]
If \( \cos \theta_0 \) is expressed in term of \( \sin \theta_0 \) (12) becomes
\[
\frac{d^2}{V_2 \sin \varphi \sqrt{e + a}} = \sqrt{1 - \left( \frac{2xd}{V_2 (e + a)} \right)^2} \tag{14}
\]
squaring both sides of (14)
\[
\frac{d^2}{V_2^2 \sin^2 \varphi \left[ \frac{e}{e + a} \right]^2} = 1 - \frac{(2xd)^2}{V_2^2 (e + a)^2} \quad \text{and} \tag{15}
\]
\[
\frac{d^3 e^2 - \sin^2 \varphi \left[ V_2^2 (e + a)^2 - (2xd)^2 \right]}{V_2^2 (e + a)^2 \sin^2 \varphi} = 0 \tag{16}
\]
is obtained.

In this last equation e, a and d are dependent on X and Z. The refractor in the X; Z plane is expressed as \( Z = AX + B \). When Z is replaced by \( AX + B \) in the equation (12) an equation dependent only on X is obtained.

Abscissa of the point at which the ray reaches the refractor under critical angle is one of the roots of equation (16). To solve the equation (13) it should be arranged with respect to X.

From (9) it can be written
\[
d^2 = d_2 X^2 + d_1 X + d_0
\]
where
\[
d_2 = (V_0 KA)^2
\]
\[
d_1 = 2 V_0^2 KA (KB + 1)
\]
\[
d_0 = V_0^2 (K^2 B^2 + 2 KB + 1) \tag{17}
\]
Similarly, using (10) and (11)
\[
a = a_1 x^2 + a_1 x
\]
where
\[ a^1_2 = 2 K (A \cos \varphi - \sin \varphi) \]
\[ a^1_1 = 2 \cos \varphi (BK + 1) \]  
\[ a^2 = (a^1_2)^2 \]
\[ e = e^1_2 x^2 + e^1_1 x + e^0_1 \]
where
\[ e^1_2 = K \sin \varphi (1 + A^2) \]
\[ e^1_0 = 2 A \sin \varphi (1 + KB) \]
\[ e^0_0 = B \sin \varphi (2 + KB) \]  
(19)  

In this stage if the terms \( d^2 e^2 \) and \((a + e)^2\) will be arranged with respect to the powers of \( X \), equation (16) should also be written in the powers of \( X \).
\[ e^2 = (e^1_2 x^2 + e^1_1 x + e^0_1)^2 = e^4 x^4 + e^3 x^3 + 3 e^2 x^2 + e^1 x + e_0. \]  
When the similar terms are equated:
\[ e^4 = (e^1_2)^2 \]
\[ e^3 = 2 e^1_2 e^1_1 \]
\[ e^2 = (e^1_1)^2 + 2 e^1_2 e^1_0 \]
\[ e^1 = 2 e^1_1 e^0_1 \]
\[ e^0 = (e^0_0)^2 \]  
(20)  

Because \( d^2 e^2 \) is the sixth power of \( X \); \( d^2 e^2 = e^4 d^2 x^6 + (e^4 d^1_1 + e^3 d^1_2) x^5 + (e^3 d^0_0 + e^2 d^1_1 + e^1 d^2_1 + e^0 d^2_2) x^4 + (e^2 d^0_0 + e^1 d^1_1 + e^0 d^2_2) x^3 + (e^1 d^0_0 + e^0 d^1_1) x + e^0 d^0_0. \) On the other hand, when \( a^2 = 0 \) is taken into account the following equation can be obtained by using equations (18), (20)
\[ (a + e)^2 = e^4 x^4 + (e^3 + 2 a^1_1 e^1_2) x^3 + (a^2 + e_2 + 2 a^1_1 e^1_1) x^2 + (e^1 + 2 a^1_1 e^1_0) x + e_0 \]
Accordingly when a polynomial in power six is written as:
\[ \sum_{n=0}^{6} P_n X^n \]  
(21)
coefficients of (21) can be as follows using equations (12)–(20)

\[ P_6 = e_4 d_2 \]

\[ P_5 = e_4 d_1 + e_5 d_2 \]

With \( f_1 = e_4 d_0 + e_5 d_1 + e_2 d_2; f_2 = e_5 d_0 + e_2 d_1 + e_1 d_2 \)

\[ P_4 = f_1 - \sin^2 \varphi V_2 e_4 + 4 \sin^2 \varphi d_1 \]

\[ P_3 = f_2 - \sin^2 \varphi V_2 (e_3 + 2 a_1 e_3' + 4 \sin^2 \varphi d_1) \]

With \( g_1 = e_2 d_0 + e_1 d_1 + e_0 d_2; g_2 = a_2 + e_2 + 2 a_1 e_1' \)

\[ P_2 = g_1 - \sin^4 \varphi V_2^2 g_2 + 4 d_0 \sin^2 \varphi \]

\[ P_1 = e_1 d_0 + e_0 d_1 - V_2^2 (e_1 + a_1 e_3') \sin^2 \varphi \]

\[ P_0 = e_0 d_0 - V_2^2 e_0 \sin^2 \varphi \]

When \( p \) values found in equations (22) are replaced in the equation (21) the smallest root of (21) will provide the abscissa value of the point of incidence. The other roots form the trivial solutions.

It goes without saying that it is tedious and not practical to solve the problem through the equation (21). But we can try an approximate solution, sufficiently accurate, which replace favourably the equation (21).

**Approximate Solution:** Under the common conditions the \( V_0; V_2 \) and \( B \) parameters are more than 1 and \( \sin \varphi, K \) parameters are less than 1 in the polinominal (21). Therefore coefficients \( P_2; P_1 \) and \( P_0 \) are great and other coefficients are negligible.

Then, putting \( \alpha = P_2; \beta = P_1 \) and \( \gamma = P_0 \)

\[ X = \frac{-\beta - \sqrt{\beta^2 - 4\alpha\gamma}}{2\alpha} \] is the approximate solution \( 23 \)

**Calculation of Time:** Fig (1)

Replacing the values \( \theta_1 = -\varphi + \arcsin \left( \frac{V_0 (1 + KZ)}{V_2} \right) \) \( 24 \)

and \( \theta_0 = \arcsin \left[ \frac{\sin \theta_1}{1 + KZ} \right] \) in the equation \( t = \frac{1}{K V_0} \left[ \log \left( \tan \frac{\theta_1}{2} \right) \right]^{\theta_1}_{\theta_0} \) \( 25 \)

time value \( t \) can be calculated easily between \( 0 \) and \( M \)
Computation of the Coordinates on the Negative x Direction:

Coordinates may be calculated from the coefficients \( P \), obtained from (22) by keeping \( V_0 \); \( B \); \( K \) values unchanged and putting \(- \varphi\) for \( \varphi \) \( X \) value found should be multiplied by \(-1\).

Numerical Computation:

The input values are:

\[
\begin{align*}
V_0 &= 1000 \, \text{m/s} \\
V_2 &= 2000 \, \text{m/s} \\
B &= 400 \, \text{m} \\
\varphi &= 5^\circ \\
K &= 0.0008333 \\
\end{align*}
\]

From (22) the coefficients of the sixth order polynomial:

\[
\begin{align*}
P_6 &= 0,2847 \times 10^{-10} \\
P_5 &= 0,1057014 \times 10^{-5} \\
P_4 &= 0,010164 \\
P_3 &= 1,705931 \\
P_2 &= -14482,8 \\
P_1 &= -6064908 \\
P_0 &= 1156219 \times 10^4 \\
\end{align*}
\]

give as smallest root \( x = 266,28 \, \text{m} \).

From \((Z = AX + B)\), \( Z \) is found \( 423,29 \, \text{m} \).

Using the formula (24) the value obtained for

\[
\text{Sin} \left( \theta_1 + \varphi \right) = 0,676364
\]

At the point of incidence \( V_0 \left( 1 + KZ \right) / V_2 = 0,676366 \)

Thus, it is proved that \( \text{Sin} \left( \theta_1 + \varphi \right) \) is equal to

\( V_0 \left( 1 + KZ \right) / V_2 \) with an error of \( 0,0001 \)

Approximate solution:

The formula (23) gives:

\[
\begin{align*}
X &= 265,24 \, \text{m} \\
Z &= 423,20 \, \text{m} \\
\end{align*}
\]
As we can see approximation is perfect.

**Time Calculation:** Can be easily performed by using (25).

Between (0;0) and (266.28; 423.29) Fig (1)

\[ t_{OM} = 0.427 \text{ Sec.} \]

Using \( \sin \theta_0 = \frac{\sin \theta_2}{1 + KZ} \)

\[ \frac{1}{K \sin \theta_0} (\cos \theta_0 - \cos \theta_2) = 359.1 \text{ m} \]

\[ t_{MO_1} = 0.474 \text{ Sec. is obtained.} \]
